WINDOWS AND LINUX · ALPHA

Most of the Mac app, now on Windows and Linux

The Windows and Linux app gains nearly everything the Mac has had: search across your files, a daily review, selection actions, People and Projects, and more. Your library still moves between all three.

Settings → Overview on Windows, with the demo library. Start here: it lists every feature, whether it's on, and one click to set it up.

Find

Files: search the folders you choose by what's in them. **Screens by meaning**, and screen text in more scripts. **Coding-agent sessions** from Claude Code and Codex, once you opt in.

Understand

Overnight review of yesterday on Today. **People, Projects and Actions** gather what's open from your meetings. **Personal Context** holds what you told LokalBot and what it learns.

Act

Selection actions rewrite, translate or summarize selected text. **Spoken summaries**, **routines and exports** to a folder or Obsidian, and **agent handoff** for actions.

Reach it fast

Ctrl+K opens the command palette. **Ctrl+Shift+Space** asks from any app, and **Ctrl+Alt+Space** acts on a selection. Both shortcuts are off until you turn them on.

Phones and tablets

A computer can now host paired phones and tablets, in Settings → Phones & tablets, over your local network or Tailscale. The apps aren't in the App Store or Play Store yet, so there's nothing to pair for now.

Autocomplete on Wayland

Suggestions in other apps on Sway, Hyprland and GNOME, as an input method. It has its own guide.

WHAT IT READS, KEEPS AND SENDS

Stays on this computer

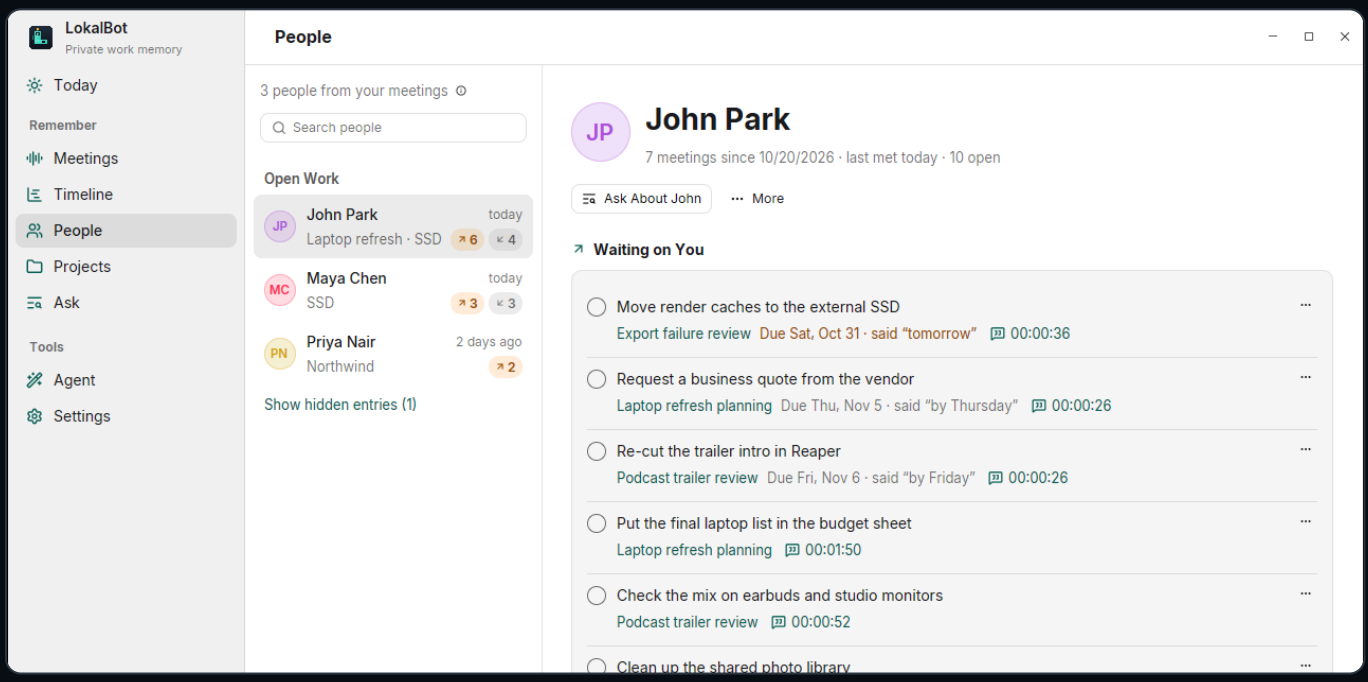

Files, screen text and reviews are read and indexed here, in your library. Screen text in other scripts uses Tesseract on Linux and Windows' own recognizer on Windows. Tesseract's language data is a separate download, once.

Leaves only if you set it up

The overnight review waits for mains power and uses a remote Think model only at a server you approved. A phone's Ask gets no personal context, work memory or files.

WHAT CHANGES WHEN YOU UPDATE

- The overnight review starts running, as on the Mac. Turn it off in Settings → Overview.
- Think and Agent Mode refuse plain `http://` to any server that isn't this computer, including ones on your network or Tailscale. Move those to HTTPS.
- Ask chats are now encrypted. Without a credential store, new chats stay in memory and a banner says so.
- Coding-agent sessions need you to opt in, even if a saved setting says they're on. A library moved from a Mac starts opted out.

People on Windows, with the demo library's made-up names.

LIMITS

- Gmail in meeting briefs is still Mac-only, as are speech runtimes such as Granite and Nemotron.
- Remembered speakers only suggest names here. They don't name anyone on their own.
- Files doesn't read `.doc`, RAW photos, or scans stored as JBIG2, CCITT or JPEG 2000. Video frames, HEIC and AVIF need ffmpeg.
- Still alpha, and the Windows app isn't code-signed. This release was tested on an automated Windows desktop, not yet by hand, and real phones on a network and real calls haven't been tried. New translations are machine-assisted.
